# Phases of the Moon (Part 2)

# Phases of the Moon I

What percentage of the Moon's surface is illuminated at 1:00 pm, 3:00 am, and 12:00 am, respectively?

A. 50%, 50%, 50%

B. 0%, 50%, 0%

C. 0%, 30%, 0%

D. 100%, 100%, 100%

# Solution

**Answer:** A

**Justification:** Fifty percent of the Moon's surface is illuminated by the Sun's light at all times, regardless of how much of the illuminated side is visible to us. Remember that the Moon's orbit is on an incline from the Ecliptic Plane. Therefore, the Earth rarely blocks any of the direct sunlight destined for the Moon. Even during a Lunar and Solar eclipse, fifty percent of the Moon remains illuminated.

# Extend Your Learning: Thought Experiment

What about a Lunar eclipse? How does light reach the Moon if the Moon is supposedly in the Earth's shadow?

Although the Earth's shadow does block all of the direct sunlight from reaching the Moon, some light is bent through Earth's atmosphere and does manage to reach the Moon's surface. By the same process that creates the beautiful reds and oranges characteristic of [sunsets](#), the light that reaches the Moon during the lunar eclipse is red shifted.

What is responsible for the phases of the Moon?

- A. The Earth's shadow is cast on a portion of the Moon
- B. The Moon spins between its dark and light sides
- C. The Sun moves behind a portion of the Moon
- D. The Moon moves behind a portion of the Sun
- E. None of the above

# Solution

**Answer:** E

**Justification:** In questions II, III, and IV in the first set on phases we determined that the phases of the Moon (or the “ball” in the questions) are the result of observing the illuminated half of the Moon from different angles. When the entire illuminated side is visible from your angle, you observe a full-moon. When half the illuminated side is visible from your angle, you see a half-moon.

# Phases of The Moon Simulation

This simulation will help you to understand the ideas in the following questions. If, at any point, you are confused about the concepts – return to this slide to try out the simulation.

# Phases of the Moon III

Which night sky corresponds to the horizon seen by the observer in the following diagram?

# Solution

**Answer:** C

**Justification:** Nearly the entire illuminated side of the moon is visible to the observer.

# Phases of the Moon IV

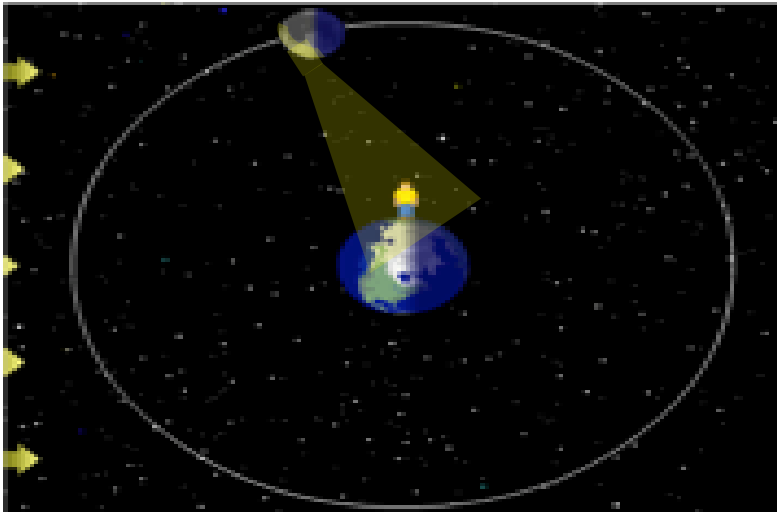

Which night sky corresponds to the horizon seen by the observer in the following diagram?

# Solution

**Answer:** B

**Justification:** Nearly the half of the illuminated side of the moon is visible to the observer. Therefore, the observer only sees the rightmost side of the half of the sphere that is facing the Earth, because the left side of the sphere has no sunlight reflecting from it.

# Phases of the Moon V

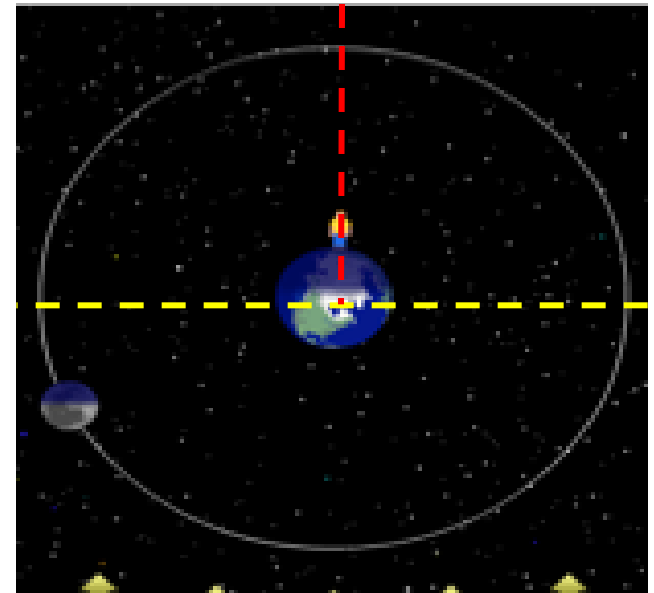

Which night sky corresponds to the horizon seen by the observer in the following diagram?

# Solution

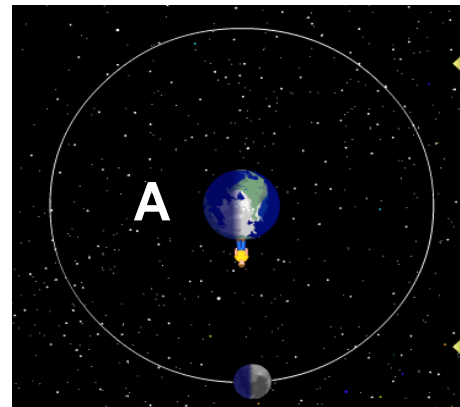

**Answer:** C

**Justification:** The Moon moves slowly enough that we can consider it to be stationary. This means that when we see the Moon and Sun each day, it is due to the rotation of the Earth. As a person standing on Earth, it is possible for you to see  $180^\circ$  range of motion. Another way to think about this is to imagine that there is a line going through the middle of the Earth (yellow line), with you standing at along a line that is at a  $90^\circ$  (red line). If the Moon falls outside of this  $180^\circ$ , it is not observable by you. Therefore, here you see no Moon in the night sky.

# Phases of the Moon VI

If an observer sees the following night sky, which diagram correctly depicts the position of the moon and observer?

# Solution

**Answer:** C

**Justification:** The Moon's position is almost over head and only half of the illuminated side of the Moon is visible from the location of the observer.

# Extend Your Learning: Video

**Title:** Phases of the Earth (from Moon)

# Phases of the Moon VII

How often do we experience a moonless night?

- A. Once a month
- B. Twice a month
- C. Every Lunar Eclipse
- D. Every Solar Eclipse

# Solution

**Answer:** A

**Justification:** We experience a moonless night once a month when the moon is closest to the sun. Moonless nights occur when the Moon is in between the Earth and the Sun, so that the Moon is entirely unobservable from the half of the globe experiencing night time.

# Phases of the Moon VIII

The Canadian Government is planning on building an observatory so that high school students can study the Moon better. They want to build the telescope in a location that maximizes the number of hours that the students can observe the Moon. In which location should they construct the observatory?

- A. South Pole
- B. North Pole
- C. Equator
- D. All locations are equal

# Solution

**Answer: D**

**Justification:** The observatory can be constructed in any of the locations, as the Moon will be observable for the same amount of time each day from any longitude on the Earth's surface. As long as the observer is on the side of the Earth that faces the Moon, they will be able to see the moon for the same amount of time regardless of longitude.

# Phases of the Moon IX

How many hours is the Moon observable from a single location on the Earth's surface over the course of one day? (Assume you have a telescope.)

- A. 12hrs
- B. 6hrs
- C. Depends on the phase of the Moon

# Solution

**Answer:** A

**Justification:** Remember this diagram from a previous question.

A person on Earth is capable of seeing a range of  $180^\circ$  (yellow line), with the person standing perpendicular to this line (red line). One rotation of the Earth is a total of  $360^\circ$  and takes approximately 24 hours to complete.

Also remember that the Moon moves so slowly that we can consider it to be stationary. Therefore our only concern is how long it takes the Earth to make one complete rotation. Knowing that a person on Earth is only capable of seeing  $180^\circ$ , which is one half of a rotation, we can determine that a person can see the Moon for one half of a rotation.

$$360^\circ / 2 = 180^\circ \rightarrow 24 / 2 = 12 \text{ hours}$$

# Phases of the Moon X

Can you ever see the moon in the sky during the day?

A. Yes

B. No

# Solution

**Answer:** Yes

**Justification:** The Moon and the Sun can be seen at the same time during the day. In fact, for fifty percent of the time the Moon is in the sky during the day time. However, because the Moon is not nearly as bright as the Sun, the Moon is not always noticeable to the naked eye.

Where is the Moon?

### Question Chooser

Choose a question to test your understanding of how the Earth-Moon-Sun geometry determines the phases of the Moon.

- ☐ Where is the Sun?
- ☒ Where is the Moon?
- ☐ What is the Moon's phase?

show answer

### Moon's Appearance
